1. Find it in start.S and check what happens after nulluser() returns. Explain what you find.
  - After nulluser returns halt is called. This means that the CPU will be set to halt until the next interrupt is fired.
2. How is XINU's way of creating and running new app processes different from UNIX/Linux?
  - Xinu creates a halted process whereas linux creates a running process. Xinu doesn't have a file system so you can't tell it to start a process based on a file, thusly you pass in a function pointer. Linux starts processes based on files.

Bonus: I have created a shell command: "ship" which will print a nice ascii viking ship for the user on the prompt.
